Topics: Extended Kalman Filter SLAM

Exercise: Implement an EKF SLAM System

Implement an extended Kalman filter SLAM (EKF SLAM) system. To support this task, we provide a small Matlab framework. The framework contains the following folders:

data contains files representing the world definition and sensor readings.
matlab contains the EKF SLAM framework with stubs to complete.
plots this folder is used to store images.

The below mentioned tasks should be implemented inside the framework in the directory matlab by completing the stubs.
After implementing the missing parts, you can run the EKF SLAM system. To do that, launch *Matlab* and change into the directory matlab. Type ekf_slam to start the main loop (this may take some time). The program plots the current belief of the robot (pose and landmarks) in the directory plots. Figure 1 depicts some example images of the state of the EKF. You can use the images for debugging and to generate an animation.

(a) Implement the prediction step of the EKF SLAM algorithm in the file prediction_step.m. Use the odometry motion model:

$$\begin{pmatrix} x_t \\ y_t \\ \theta_t \end{pmatrix} = \begin{pmatrix} x_{t-1} \\ y_{t-1} \\ \theta_{t-1} \end{pmatrix} + \begin{pmatrix} \delta_{trans} \cos(\theta_{t-1} + \delta_{rot1}) \\ \delta_{trans} \sin(\theta_{t-1} + \delta_{rot1}) \\ \delta_{rot1} + \delta_{rot2} \end{pmatrix}$$

Compute its Jacobian G_t^x to construct the full Jacobian matrix G_t:

$$G_t^x = I + \begin{pmatrix} 0 & 0 & -\delta_{trans} \sin(\theta_{t-1} + \delta_{rot1}) \\ 0 & 0 & \delta_{trans} \cos(\theta_{t-1} + \delta_{rot1}) \\ 0 & 0 & 0 \end{pmatrix}$$
Figure 1: Example images of the state of the EKF at certain time indices.

For the noise in the motion model assume

$$R_t^x = \begin{pmatrix} 0.1 & 0 & 0 \\ 0 & 0.1 & 0 \\ 0 & 0 & 0.01 \end{pmatrix}$$

(b) Implement the correction step in the file `correction_step.m`. The argument *z* of this function is a struct array containing *m* landmark observations made at time step *t*. Each observation *z(i)* has an id *z(i).id*, a range *z(i).range*, and a bearing *z(i).bearing*.

Iterate over all measurements ($i = 1,...,m$) and compute the Jacobian H_t^i. You should compute a block Jacobian matrix H_t by stacking the H_t^i matrices corresponding to the individual measurements. Use it to compute the Kalman gain and update the system mean and covariance *after* the for-loop. For the noise in the sensor model assume that Q_t is a diagonal square matrix as follows

$$Q_t = \begin{pmatrix} 0.01 & 0 & 0 & \cdots \\ 0 & 0.01 & 0 & \cdots \\ 0 & 0 & 0.01 & \cdots \\ & \vdots & & \ddots \end{pmatrix} \in \mathbb{R}^{2m \times 2m}$$

Some implementation tips:

• While debugging, run the filter only for a few steps by replacing the for-loop in `ekf_slam.m` by something along the lines of for `t = 1:50`.

• The command `repmat` allows you to replicate a given matrix in many different ways and is magnitudes faster than using for-loops.

• When converting implementations containing for-loops into a vectorized form it often helps to draw the dimensions of the data involved on a sheet of paper.

• Many of the functions in *Matlab* can handle matrices and compute values along the rows or columns of a matrix. Some useful functions that support this are `sum`, `sqrt`, and many others.
